One of the most important features of Python is its high level of support for data structures and their iterable objects (strings, numbers, and tuples). In this article, I'll show how you can use Python's list constructors to create a rich variety of useful data structures. List Constructors By default, Python's list() function creates a new empty list. You can also use list() to create a new list with a fixed length: >>> numbers = list() >>> numbers.append(1) >>> numbers.append(2) >>> numbers.append(3) >>> numbers[0] 1 >>> numbers[-1] 3 Python also provides a powerful list comprehension. You can use a list comprehension to create an empty list with a fixed length. You can also use it to add elements to the front and/or back of a list: >>> numbers = [1, 2, 3] >>> [n for n in numbers] [1, 2, 3] >>> numbers = [n for n in numbers if n > 1] [1, 2] Note: the above examples create a new list named numbers. To save typing, you can change the name of the list using the list.__setitem__() method (e.g., list.append()). Why Use Python's List Constructors? There are many reasons why you might want to use Python's list constructors. Let's start with the simple case of building a list. When you create a list, Python creates an empty list, copies all of the elements of the source list into the new list, and then returns the new list. The above example shows that you can use a list comprehension to create a list with the elements from the source list. Using Python's list constructor is a good way to create a list with a fixed size. It is also a good way to "fix" a list. For example, you can use Python 2d92ce491b
