An inset shows the frequency dependence of the optical conductivity at the charge-ordering energy in a greater detail. (\*\*\*) Schematic illustration of the formation of the charge-ordered state at the energy of the shallow donor states. The enhancement of the optical conductivity is suppressed at high energies. Since the population of the shallow donor states is reduced by the dielectric mismatch at the interfaces, the suppression of the optical conductivity is consistent with the suppression of the photocurrent in the bias voltage-dependent measurement. We have also calculated the complex dielectric constant,  $\epsilon^*(\omega) = \epsilon'(\omega) - i\epsilon''(\omega)$ , in the SRO region and the results are shown in Fig. 5(b) (ref-type="fig"). The dielectric constant at the zero frequency in SRO is almost zero as the difference between the dielectric constants of the SrTiO<sub>3</sub> substrate and the SRO layer is large. With decreasing energy, the dielectric constant of the SRO layer monotonically increases. The dielectric constant is almost constant above 0.5 eV in SRO, while it increases with increasing energy in the insulating phase. The energy dependence of the dielectric constant in SRO is consistent with the experimental observation in Fig. 1(e) (ref-type="fig"). Thus, the photocurrent in the bias voltage-dependent measurement is strongly suppressed at the charge-ordering energy due to the charge trapping by the interface, while the zero bias photocurrent is enhanced due to the decrease of the carrier density at the interface. Since the carrier density at the interface is strongly reduced by the weak dielectric mismatch, we expect
